Interaction-based STPO learning process

Well-known

Black-box

$\mathcal{M}(\mathcal{E}, \rho, t)$

π Interaction $\mathcal{E}$

t times

Update

Reports a policy that approximates

$$\pi^* = \arg\max_{\pi \in \Pi} f(\pi; \mathcal{E}),$$

selected from the generated sequence

$$\widetilde{\pi}_t \in \Pi_t = (\pi_0, ..., \pi_t) \subset \Pi$$

with unknown and non-monotonic f,

leaving some open questions:

?

- How is it selected?
- What is the magnitude of non-monotonicity?
- Is selection under this phenomenon reliable?

$\widetilde{\pi}_t$

Systematic study of selection in RL

Across different standard processes within the same well-known conditions to solve **black-box** questions
